

## 1. JVM Tasks

JVM performed three tasks, these are :

a. Load Code

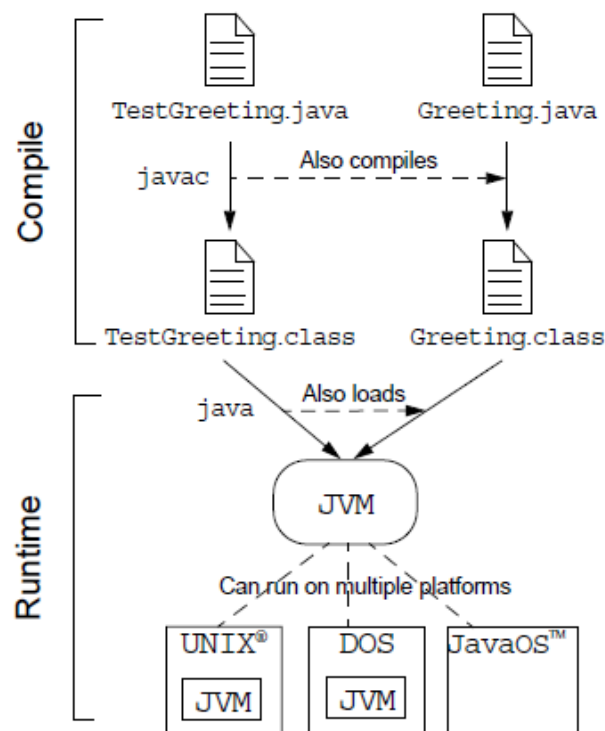

Perform by the class loader which load all classes needed for the execution of a program. It adds more security characteristics in this phase. The memory layout of the executable file is determined.

b. The Byte Code Verifier: The JVM puts the code through a byte-code verifier that test a format of code fragmentation and checks code fragments for illegal code.

c. The Verification Process : it performs the following tasks.

- The classes adhere to the class file format of the JVM specifications
- There is no access restriction violations.
- The code ensures nor operand stack overflow or underflow.
- The types of parameters for all operational codes are correct.

# Java Technology Runtime Environment

## Java Technology Runtime Environment

## 2. Object Oriented Programming

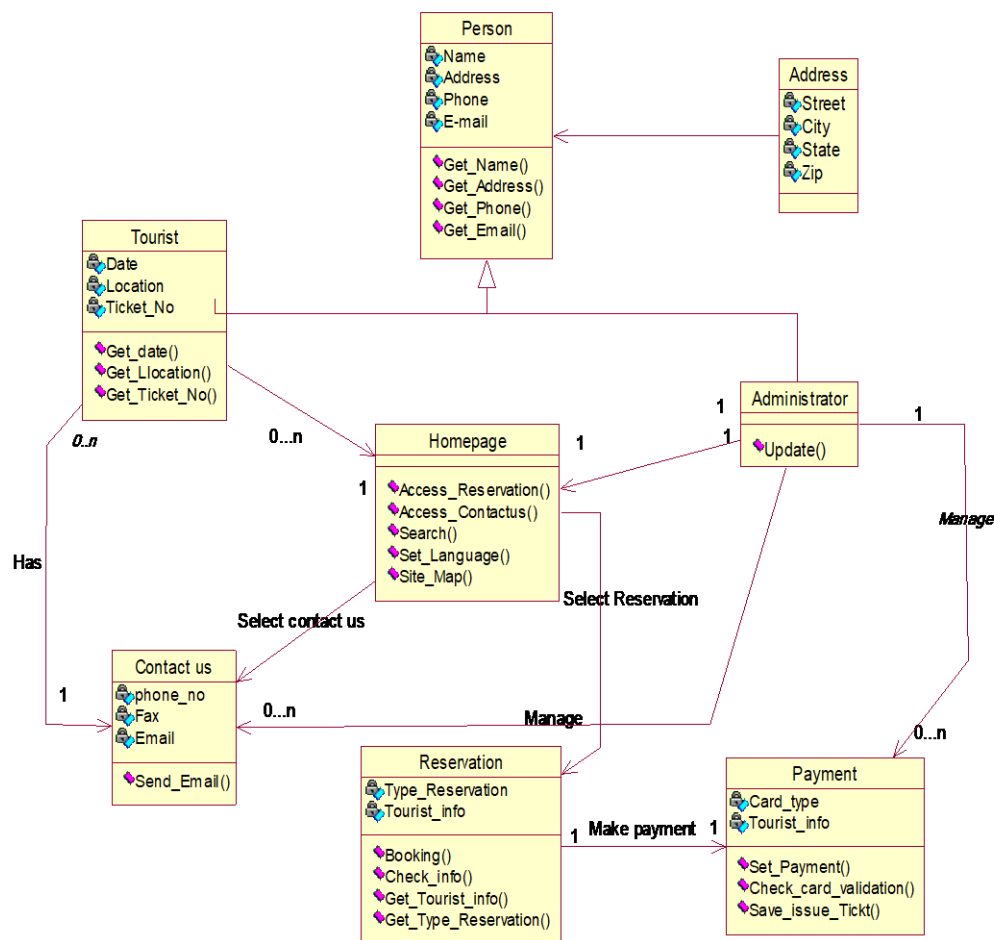

The Analysis and Design Phase :

**Analysis** describes what the system needs to do: Modeling the real-world, including actors and activities, objects, and behaviors.

**Design** describes how the system does it:

- Modeling the relationships and interactions between objects and actors in the system

**Example: E-tourism Class Diagram**

### **3. Declaring Java Technology Classes**

#### **a. The Basic syntax of a Java class:**

```
<modifier>* class <class_name> {  
    <attribute_declaration>*  
    <constructor_declaration>*  
    <method_declaration>*  
  
    } end Class
```

#### **Example**

:

```
1  public class Vehicle {  
2      private double maxLoad;  
3      public void setMaxLoad(double value) {  
4          maxLoad = value;  
5      }  
6  }
```

**Question1:** According to Syntax in above , specify class name and its modifier?

#### **b. The Default Constructor**

There is always at least one constructor in every class. If the writer does not supply any constructors, the default constructor is present automatically:

The default constructor takes no arguments and the default constructor body is empty. The default enables you to create object instances with new Xxx()without having to write a constructor.

#### **c. Basic syntax of an attribute:**

```
<modifier>* <type> <name> [= <initial_value>];
```

```
1  public class Foo {  
2      private int x;  
3      private float y = 10000.0F;  
4      private String name = "Bates Motel";  
5  }
```

**Question2:** According to Syntax in above, specify class attribute(s) and variables

#### **d. Declaring Methods**

```
<modifier>* <return_type> <name> ( <argument>* )  
{  
<statement>*  
} end method
```

```
1  public class Dog {  
2      private int weight;  
3      public int getWeight() {  
4          return weight;  
5      }  
6      public void setWeight(int newWeight) {  
7          if ( newWeight > 0 ) {  
8              weight = newWeight;  
9          }  
10     }  
11 }
```

#### **e. Accessing Object Members**

The *dot* notation is: **<object>.<member>**

- This is used to access object members, including attributes and methods.

```
public static void main (String args []) {  
    Dog d= new Dog ();  
    d.setWeight(42);  
    d.weight = 42; // only permissible if weight is public  
}
```

تعليق : ممكن ان نصل الى ال Class Dog من اي كلاس ثاني بشرط ان يكون الاول من نوع Public .

### **3. Access Control**

<i><b>Modifier</b></i>	<i><b>Same Class</b></i>	<i><b>Same Package</b></i>	<i><b>SubClass</b></i>	<i><b>Universe</b></i>
<b>private</b>	<b>Yes</b>			
<b>default</b>	<b>Yes</b>	<b>Yes</b>		
<b>protected</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	
<b>public</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>	<b>Yes</b>
